Decentralized Stabilization for a Class of Continuous-Time Nonlinear Interconnected Systems Using Online Learning Optimal Control Approach

Decentralized Stabilization for a Class of Continuous-Time Nonlinear Interconnected Systems Using Online Learning Optimal Control Approach
[\(http://blogs.cuit.columbia.edu/zp2130/files/2019/02/Decentralized-Stabilization-for-a-Class-of-Continuous-Time-Nonlinear-Interconnected-Systems-Using-Online-Learning-Optimal-Control-Approach.pdf\)](http://blogs.cuit.columbia.edu/zp2130/files/2019/02/Decentralized-Stabilization-for-a-Class-of-Continuous-Time-Nonlinear-Interconnected-Systems-Using-Online-Learning-Optimal-Control-Approach.pdf)

Neural-network-based Online Learning Optimal Control

Decentralized Control Strategy

1. Cost functions (critic neural networks) – local optimal controllers
2. Feedback gains to the optimal control policies – decentralized control strategy

Optimal Control Problem (Stabilization)

Hamilton-Jacobi-Bellman (HJB) Equations

- Apply Online Policy Iteration Algorithm (construct and train critic neural networks) to solve HJB Equations.

The **decentralized control** has been a control of choice for large-scale systems because it is computationally efficient to formulate control law that use only **locally available subsystem states** or outputs.

Though **dynamic programming** is a useful technique to solve the optimization and optimal control problems, in may cases, it is computationally difficult to apply it because of the **curse of dimensionality**.

Considering the effectiveness of ADP and **reinforcement learning** techniques in solving the **nonlinear optimal control problem**, the **decentralized control approach** established is natural and convenient.

Notation

$i = 1, 2, \dots, N$: i th subsystem.

$\mathbf{x}_i(t) \in \mathbb{R}^{n_i}$: **state** vector of the i th subsystem.

$\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_N$: **local states**.

$\bar{\mathbf{u}}_i(\mathbf{x}_i(t)) \in \mathbb{R}^{m_i}$: **control** vector of the i th subsystem.

$\bar{\mathbf{u}}_1(\mathbf{x}_1), \bar{\mathbf{u}}_2(\mathbf{x}_2), \dots, \bar{\mathbf{u}}_N(\mathbf{x}_N)$: **local controls**.

$\mathbf{u}_i(\mathbf{x}_i), i = 1, 2, \dots, N$: **control policies**.

$f_i(\mathbf{x}_i)$: **nonlinear internal dynamics**.

$g_i(\mathbf{x}_i)$: **input gain matrix**.

$g_i(x_i)\bar{Z}_i(x)$: **interconnected term**. $Z_i(x)$'s x has no i .

$R_i \in \mathbb{R}^{m_i \times m_i}, i = 1, 2, \dots, N$: **symmetric positive definite matrices**.

ρ : nonnegative constants.

$h_{ij}(x_j)$: **positive semidefinite function**.

$Q_i(x_i), i = 1, 2, \dots, N$: **positive definite functions** satisfying $h_i(x_i) \leq Q_i(x_i), i = 1, 2, \dots, N$.

$\mu_i(\mathbf{x}_i)$: **control policy**.

Ω_i : $f_i + g_i u_i$ is Lipschitz continuous on a set Ω_i in \mathbb{R}^{n_i} containing the origin, and the subsystem is controllable in the sense that there exists a continuous control policy on Ω_i that asymptotically stabilizes the subsystem.

Decentralized Control Problem of the Large-Scale System

Paper studies a class of continuous-time nonlinear large-scale systems: composed of **N interconnected subsystems** described by

$$\dot{\mathbf{x}}_i(t) = f_i(\mathbf{x}_i(t)) + g_i(\mathbf{x}_i(t)) (\bar{\mathbf{u}}_i(\mathbf{x}_i(t)) + \bar{Z}_i(\mathbf{x}(t))) \quad (1)$$

$$i = 1, 2, \dots, N$$

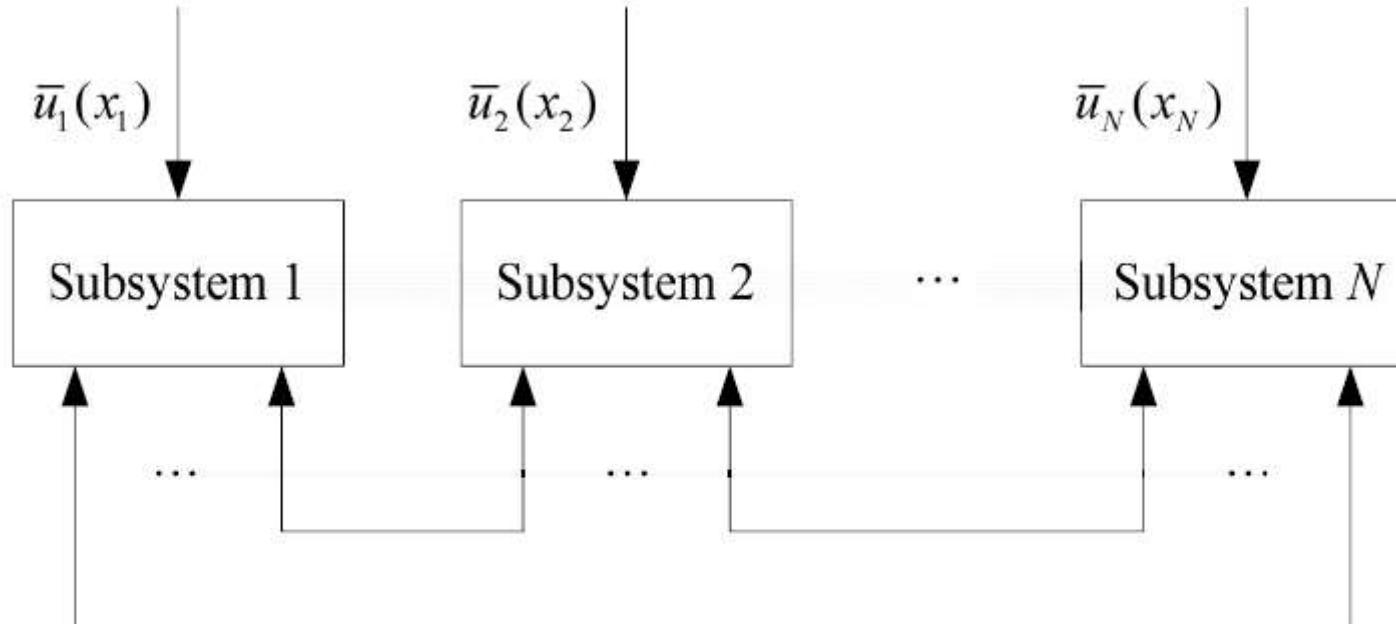

Fig. 1. Structural diagram of the decentralized control problem of the interconnected system.

$\mathbf{x}_i(0) = \mathbf{x}_{i0}$: initial state of the i th subsystem,

Assumption 1: When $\mathbf{x}_i = 0$, i th subsystem is **equilibrium**.

Assumption 2: $f_i(\mathbf{x}_i)$ and $g_i(\mathbf{x}_i)$ are differentiable in arguments with $f_i(0) = 0$.

Assumption 3: When $\mathbf{x}_i = 0$, the **feedback control** vector $\bar{\mathbf{u}}_i(\mathbf{x}_i) = 0$.

$$Z_i(x) = R_i^{1/2} \bar{Z}_i(x)$$

where

$$\textcolor{brown}{R}_i \in \mathbb{R}^{m_i \times m_i}, i = 1, 2, \dots, N. : \textbf{symmetric positive definite matrices}.$$

$$\textcolor{violet}{Z}_i(x) \in \mathbb{R}^{m_i}, i = 1, 2, \dots, N.$$

are bounded as follows:

$$\|\textcolor{violet}{Z}_i(x)\| \leq \sum_{j=1}^N \rho_{ij} \textcolor{brown}{h}_{ij}(x_j), \quad (2)$$

$$i = 1, 2, \dots, N.$$

Define

$$h_i(x_i) = \max \{h_{1i}(x_i), h_{2i}(x_i), \dots, h_{Ni}(x_i)\}$$

then (2) can be formulated as

$$\|Z_i(x)\| \leq \sum_{j=1}^N \lambda_{ij} \textcolor{brown}{h}_j(\textcolor{brown}{x}_j), \quad i = 1, 2, \dots, N.$$

where

$$\lambda_{ij} \geq \frac{\rho_{ij} h_{ij}(x_j)}{h_j(x_j)}$$

C1 – Optimal Control of Isolated Subsystems (Framework of HJB Equations)

C2 – Decentralized Control Strategy

Consider the N isolated subsystems corresponding to (1)

$$\dot{x}_i(t) = \textcolor{brown}{f}_i(x_i(t)) + \textcolor{violet}{g}_i(x_i(t)) (\textcolor{red}{u}_i(x_i(t))) \quad (4)$$

$$i = 1, 2, \dots, N$$

Find the **control policies** $\textcolor{red}{u}_i(\textcolor{blue}{x}_i), i = 1, 2, \dots, N$ which **minimize** the **local cost functions**

$$\textcolor{brown}{J}_i(x_{i0}) = \int_0^\infty \{Q_i^2(x_i(\tau)) + u_i^T(\textcolor{blue}{x}_i(\tau)) \textcolor{brown}{R}_i u_i(\textcolor{blue}{x}_i(\tau))\} d\tau \quad (5)$$

$$i = 1, 2, \dots, N$$

(How to get the equation 5 ? Should $\mathbf{Q} = \mathbf{Q}$ and $\mathbf{R} = \mathbf{P}$, (\mathbf{Q} and \mathbf{P} ∈ Lyapunov Equation) ?)

to deal with the infinite horizon **optimal control problem**.

where

$Q_i(x_i), i = 1, 2, \dots, N.$: **positive definite functions** satisfying

$$\textcolor{brown}{h}_i(x_i) \leq Q_i(x_i), i = 1, 2, \dots, N. \quad (6)$$

Based on optimal control theory, feedback controls (**control policies**) must be **admissible**, i.e., stabilize the subsystems on Ω_i , guarantee **cost function (5) are finite**.

Admissible Control

Definition 1

Consider the isolated subsystem i,

$$\begin{aligned} \mu_i &\in \Psi_i(\Omega_i) \\ \mu_i(0) &= 0 \\ u_i(x_i) &= \mu_i(x_i) \end{aligned}$$

For any set of admissible **control policies** $\mu_i \in \Psi_i(\Omega_i), i = 1, 2, \dots, N$, if the associated **cost functions**

$$\textcolor{blue}{V}_i(x_{i0}) = \int_0^\infty \{Q_i^2(x_i(\tau)) + \mu_i^T(x_i(\tau)) R_i \mu_i(x_i(\tau))\} d\tau \quad (7)$$

$$i = 1, 2, \dots, N.$$

are continuously differentiable, then the infinitesimal versions of (7) are the so-called **nonlinear Lyapunov equations**

$$0 = Q_i^2(x_i) + \mu_i^T(x_i) R_i \mu_i(x_i) + (\nabla \textcolor{blue}{V}_i(x_i))^T (\textcolor{brown}{f}_i(x_i)) + \textcolor{violet}{g}_i(x_i) \mu_i(x_i) \quad (8)$$

(How to get the equation 8 ? Should $\mathbf{Q} = \mathbf{Q}$ and $\mathbf{R} = \mathbf{P}$, (\mathbf{Q} and \mathbf{P} ∈ Lyapunov Equation) ?)

where

$$\begin{aligned}\textcolor{blue}{V}_i(0) &= 0 \\ \nabla \textcolor{blue}{V}_i(x_i) &= \frac{\partial \textcolor{blue}{V}_i(x_i)}{\partial x_i} \\ i &= 1, 2, \dots, N.\end{aligned}$$

Lyapunov Equation

Linear Quadratic Lyapunov Theory (<https://blogs.cuit.columbia.edu/zp2130/files/2019/02/lq-lyap.pdf>)

Linear Quadratic Lyapunov Theory Notes (<http://blogs.cuit.columbia.edu/zp2130/files/2019/02/lq-lyap-notes.pdf>)

Lyapunov Equation

We assume $\textcolor{blue}{A} \in \mathbb{R}^{n \times n}$, $\textcolor{brown}{P} = \textcolor{brown}{P}^T \in \mathbb{R}^{n \times n}$. It follows that $\textcolor{violet}{Q} = \textcolor{violet}{Q}^T \in \mathbb{R}^{n \times n}$.

Continuous-time linear systems: for $\dot{x} = \textcolor{blue}{A}x$, $V(z) = z^T \textcolor{brown}{P}z$, we have $\dot{V}(z) = -z^T \textcolor{violet}{Q}z$ where $\textcolor{brown}{P}$, $\textcolor{violet}{Q}$ satisfy (continuous-time) Lyapunov Equation: $\textcolor{blue}{A}^T \textcolor{brown}{P} + \textcolor{brown}{P} \textcolor{blue}{A} + \textcolor{violet}{Q} = 0$

If $\textcolor{brown}{P} > 0$, $\textcolor{violet}{Q} > 0$, then system is (globally asymptotically) **stable**.

If $\textcolor{brown}{P} > 0$, $\textcolor{violet}{Q} \geq 0$, and $(\textcolor{violet}{Q}, \textcolor{blue}{A})$ observable, then system is (globally asymptotically) **stable**.

$$\textcolor{blue}{A}^T \textcolor{brown}{P} + \textcolor{brown}{P} \textcolor{blue}{A} + \textcolor{violet}{Q} = 0$$

where $\textcolor{blue}{A}$, $\textcolor{brown}{P}$, $\textcolor{violet}{Q} \in \mathbb{R}^{n \times n}$, and $\textcolor{brown}{P}$, $\textcolor{violet}{Q}$ are **symmetric**

interpretation: for linear system

$$\dot{x} = \textcolor{blue}{A}x$$

if

$$V(z) = z^T \textcolor{brown}{P}z$$

$$V(z) = \textcolor{brown}{z}^T \textcolor{brown}{P}z$$

then

$$\dot{V}(z) = (\textcolor{blue}{A}z)^T \textcolor{brown}{P}z + z^T \textcolor{brown}{P}(\textcolor{blue}{A}z) = -z^T \textcolor{violet}{Q}z$$

$$\dot{V}(z) = (\textcolor{blue}{A}z)^T \textcolor{brown}{P}z + z^T \textcolor{brown}{P}(\textcolor{blue}{A}z) = -\textcolor{violet}{z}^T \textcolor{violet}{Q}z$$

i.e., if $\textcolor{brown}{z}^T \textcolor{brown}{P}z$ is the (generalized) **energy**, then $\textcolor{violet}{z}^T \textcolor{violet}{Q}z$ is the associated (generalized) **dissipation**

Lyapunov Integral

If $\textcolor{blue}{A}$ is **stable** there is an explicit formula for **solution** of **Lyapunov equation**:

$$\textcolor{brown}{P} = \int_0^\infty e^{t \textcolor{blue}{A}^T} \textcolor{violet}{Q} e^{t \textcolor{blue}{A}} dt$$

to see this, we note that

$$\begin{aligned}\textcolor{blue}{A}^T \textcolor{brown}{P} + \textcolor{brown}{P} \textcolor{blue}{A} &= \int_0^\infty \left(\textcolor{blue}{A}^T e^{t \textcolor{blue}{A}^T} \textcolor{violet}{Q} e^{t \textcolor{blue}{A}} + e^{t \textcolor{blue}{A}^T} \textcolor{violet}{Q} e^{t \textcolor{blue}{A}} \textcolor{blue}{A} \right) dt \\ &= \int_0^\infty \left(\frac{d}{dt} e^{t \textcolor{blue}{A}^T} \textcolor{violet}{Q} e^{t \textcolor{blue}{A}} \right) dt \\ &= e^{t \textcolor{blue}{A}^T} \textcolor{violet}{Q} e^{t \textcolor{blue}{A}} \Big|_0^\infty \\ &= -\textcolor{violet}{Q}\end{aligned}$$

Interpretation as cost-to-go

If $\textcolor{blue}{A}$ is **stable**, and $\textcolor{brown}{P}$ is (unique) solution of

$$\textcolor{blue}{A}^T \textcolor{brown}{P} + \textcolor{brown}{P} \textcolor{blue}{A} + \textcolor{violet}{Q} = 0$$

, then

 Invalid Equation

thus $V(z)$ is **cost-to-go** from point z (with no input) and **integral quadratic cost function** with matrix $\textcolor{violet}{Q}$

If $\textcolor{blue}{A}$ is **stable** and $\textcolor{violet}{Q} > 0$, then for each t , $e^{t \textcolor{blue}{A}^T} \textcolor{violet}{Q} e^{t \textcolor{blue}{A}} > 0$, so

$$\textcolor{brown}{P} = \int_0^\infty e^{t \textcolor{blue}{A}^T} \textcolor{violet}{Q} e^{t \textcolor{blue}{A}} dt > 0$$

meaning: if \mathbf{A} is **stable**,

- we can choose **any positive definite** quadratic form $z^T \mathbf{Q} z$ as the dissipation, i.e., $-\dot{V} = z^T \mathbf{Q} z$
- then solve a set of linear equations to find the (unique) quadratic form $\dot{V} = z^T \mathbf{Q} z$
- \mathbf{V} will be positive definite, so it is a **Lyapunov function** that proves \mathbf{A} is **stable**.

In particular: a **linear system** is **stable** if and only if there is a **quadratic Lyapunov function** that proves it.

Evaluating Quadratic Integrals

Suppose $\dot{x} = \mathbf{A}x$ is **stable**, and define

$$J = \int_0^\infty x(t)^T \mathbf{Q} x(t) dt$$

to find J , we solve **Lyapunov equation**

$$\mathbf{A}^T \mathbf{P} + \mathbf{P} \mathbf{A} + \mathbf{Q} = 0$$

for \mathbf{P} then,

$$J = x(0)^T \mathbf{P} x(0)$$

In other words: we can evaluate **quadratic integral** exactly, by solving a set of **linear equations**, without even computing a matrix exponential.

Online Policy Iteration Algorithm (Critic Networks)

Solve HJB Equations
